1. Introduction

There has been a long history of coastal protection in Christchurch Bay. The Bay is characterised by soft cliffs which are vulnerable to erosion by wave attack. The construction of cliff-top property during the 20th century has created the need to prevent or reduce the rate of erosion and has resulted in cliff stabilisation work and the construction of coast protection measures. The assets which constitute the coast protection measures consist of a combination of along-shore defences and cross-shore structures. Along-shore defences, such as revetments and seawalls, protect the toe of the cliff from wave attack by dissipating or reflecting wave energy. Cross-shore structures such as timber and rock groynes are designed to interrupt long-shore drift and maintain a beach which provides a natural defence to wave attack.

The coastal frontage in Christchurch Bay extends across the boundaries of three Coast Protection Authorities; Bournemouth Borough Council, Christchurch Borough Council and New Forest District Council. Historically, work has been carried out on a District level, in response to local demands on the coastline. This approach to coastal protection has led to there being varying degrees of protection around the Bay and has resulted in an irregular coastal profile. In addition, structures have contributed to the interruption of and reduction in the amount of material in the coastal system, thus increasing erosion at other locations in the Bay and increasing the need for further coastal protection structures.

Due to the morphology of Christchurch Bay wave conditions vary along the coastline. The design of coastal assets has taken these factors into account. Consequently an assortment of types and styles of asset have been implemented around the Bay. The type of assets utilised have also varied due to the availability of funding, construction materials, as well as the variable environmental considerations and social issues. Due to changing requirements and demands on the coastline, varying coastal protection measures have been implemented at differing times over the last century. These assets have deteriorated over time and subsequently been subject to maintenance and replacement work. This has resulted varying conditions of defences and structures around the Bay, from very good to very poor condition.

Figure 1.1 Rock strongpoint at Highcliffe

Figure 1.2 Timber groyne & seawall at Milford-on-Sea

The condition of all assets has been evaluated for the Christchurch Bay Strategy Study in order to establish a baseline of what the current condition level is. By assessing the present condition of the asset an estimate on the residual life can be generated should maintenance be terminated under a 'Do Nothing' scenario. Depending on the location, following the failure an asset, cliff erosion is likely to ensue. This provides a starting point from which to introduce future cliff erosion scenarios in order to assess when cliff top property is likely to be affected. Furthermore, existing coast protection measures can be evaluated in terms of maintenance requirements with regard to possible future management options.

2. Methodology

2.1. AIMS

This Strategy aims to evaluate Christchurch Bay as a single coastal cell. This concept has been adopted for referencing of coast protection measures within the Bay. At present the numbering of assets has been referenced locally on a district level. This means that the location of individual defences or structures cannot be correctly identified from a bay-wide standpoint, or a national perspective. The Strategy therefore adopted a method of referencing which has been developed for the National Flood and Coastal Defence Database (NFCDD). The NFCDD project is a single, easily accessible and definitive store for all data on flood and coastal assets in England and Wales. The development of NFCDD is a requirement under DEFRA's High Level Targets (Target 4A) for Flood and Coastal Defence, published in November 1999.

In NFCDD the entire coastline is referenced with respect to the particular along-shore defence, for example a length of seawall or revetment. Each cross-shore structure (eg. groyne) is then referenced according to whichever defence it relates to (i.e. is perpendicular to, or "hangs" from). The defences become components of the frontage unit which correlate with Shoreline Management Plan (SMP) Management Units. However, in contrast to the SMP, the units are numbered in a clockwise direction around the coast. NFCDD referencing also makes provision for this through the individual ownership and management of Frontage Units and Sub Units (Table 2.1).

| NFCDD Reference Coding Format | Example |
|-------------------------------|---------|
| Region Number | 7 |
| Area Number | 1 |
| Sub-area Number | Blank |
| Frontage | R906 |
| Frontage Unit | 02 |
| Frontage Sub-unit | 1 |
| Coastal Indicator | C |
| Defence Number | 04 |
| Structure Reference | 001 |

Table 2.1 Example of the format used in NFDCC for coastal references

A specific assessment method, the condition assessment checklist, was developed for this Strategy and incorporated the Environment Agency visual condition assessment criteria published in the National Sea & River Defence Surveys Condition Assessment Manual. This enabled a visual assessment to be undertaken to determine the overall condition of the asset. As the inspections of the assets were carried out on site, a spreadsheet was developed which enabled items to be individually assessed. The spreadsheets were designed with the aim of being able assess the condition of the asset by visual assessment using the condition checklist. This approach was adopted in order that an engineer could carry out the assessment in a non-subjective manner. Individual spreadsheets have been developed for all assets (concrete seawall; rock revetment; timber groynes; rock groynes / strongpoints), each of which is presented in Appendix A (Table A.1 to A.5).

2.2 ASSET CONDITION ASSESSMENT PROCEDURE

2.2.1. Field apparatus

Digital camera (plus spare camera cards and batteries) Aerial photograph map book Fieldwork sheets

2.2.2. Asset inspections

Using fieldwork sheets, an individual assessment of all assets was undertaken in the field. Depending on what was highlighted in the checklist, each defence or structure was assigned a score to represent the overall condition of the asset. By using the spreadsheets the process of assessing the assets could be undertaken with a low level of subjectivity.

Each Asset was assessed using the following scoring system:

| Very good | - | Condition 1 | (colour blue) |
|-----------|---|-------------|---------------------|
| Good | - | Condition 2 | (colour light blue) |
| Fair | - | Condition 4 | (colour yellow) |
| Poor | - | Condition 4 | (colour orange) |
| Very poor | - | Condition 5 | (colour red) |

When multiple elements make up an Asset, the overall score is taken from the worst scoring element within the Asset. Where possible, photographs were taken of each Asset.

2.2.3. Asset location

The location of each 'along shore' defence was established by identifying the start and end point of the defence using an up-to-date aerial photograph within a GIS layer. Once identified, each defence was named in accordance with the NFCDD numbering system. Subsequently, each 'cross shore' structure could then be numbered according to the relevant 'along shore' defence reference.

2.3 CONDITION ASSESSMENT

Asset inspections were conduced along the Christchurch Bay frontage in August 2003. The section of coastline measured 16.4 km from Hengistbury Head to Hurst Spit Castle Point, contained 114 along-shore defences and 94 cross-shore structures. Table 2.2 (below) provides a summary of the combined condition for all Assets.

| ASSET ELEMENT | | | | | | TOTAL |
|----------------------|--------------|------|------|------|--------------|-------|
| | 1 | 2 | 3 | 4 | 5 | |
| | Very Good | Good | Fair | Poor | Very Poor | |
| Defences (revetment) | 16 | 69 | 27 | 2 | 0 | 114 |
| Structures (groynes) | 21 | 47 | 21 | 5 | 0 | 94 |

Table 2.2 Combined condition summary for all assets

Table 2.2 indicates that of the 94 Structures (e.g. groynes), 89 were of condition 3 or better (95%), and 5 were of condition 4 or 5 (9%). In general the majority of the defences and structures have been classed as OK to new/very good condition.

Table 2.3 details the combination of the defence and structure condition rating.

| | | Defence C | Defence Condition | | | | | |
|-----------|------|-----------|-------------------|----|---|---|------|--|
| | | 1 | 2 | 3 | 4 | 5 | None | |
| | 1 | 2 | 14 | 5 | | | | |
| tion | 2 | 7 | 26 | 10 | | | 4 | |
| Condition | 3 | 2 | 12 | 4 | 1 | | 2 | |
| | 4 | | 2 | 2 | 1 | | | |
| Structure | 5 | | | | | | | |
| · | None | 5 | 15 | 6 | | | | |

Table 2.3 defence and structure rating

Table 2.3 indicates that there were only 2 records of both defence and structure being awarded condition 1 status, and 12 records where defences were of condition 2 and structures of condition 3. The combination of structures and defences in condition 1 or 2 totalled 49 whereas the combination of structures and defences in condition 4 or 5 totalled 1.

2.4 RESIDUAL LIFE

Following the generation of condition values for all the Assets, each Asset was evaluated in terms of its residual life, if a 'Do Nothing' scenario was adopted and all maintenance work ceased. This is the estimated amount of time that it would take until the Asset degrades to such a level that it offers little or no value as a coast protection measure (i.e. when the Asset effectively becomes a condition 5). The time interval is based on the likely serviceable life-span of a particular Asset from new, less the time it is estimated to have taken for the Asset to attain its present condition. The serviceable life of all Assets within the Bay is based upon a working knowledge of what the expected life-span of particular structures and defences is likely to be in view of the possible conditions and level of energy in the system. The residual life is expressed as a future date by adding the estimated time it would take to become a condition 5 to the present date (yr 2003). Table 2.4 (below) provides details of what the estimated residual life expectancy of particular Assets is likely to be, relative to the condition of the Asset.

| | Asset condition / estimated residual life of Asset | | | | | | | |
|------------|--|--|----------|---------|---------|--|--|--|
| | 1 | 1 2 3 4 5 | | | | | | |
| Concrete / | | | | | | | | |
| steel | 30 years | 20 years | 10 years | 5 years | 2 years | | | |
| Mendip | | | | | | | | |
| limestone | 30 years 20 years 10 years 5 years 2 years | | | | | | | |
| Portland | | | | | | | | |
| limestone | 20 years | 20 years 15 years 10 years 5 years 2 years | | | | | | |
| Hardwood | 10 years | 5 years | 3 years | 2 years | 1 years | | | |

Table 2.4 Estimated residual life expectancies

Details of all condition assessments and estimated residual life calculations for all Assets are produced in Table B1 in Appendix B and illustrated in aerial photograph overlays in Figure B.1 to B.9. Table B1 indicates that currently 25% of 'cross-shore' structures will need replacing between 2003 (year 0 of strategy study) and 2023 whereas only 6% of 'along shore' defences will need replacing before 2023.

3. Beach Profile Analysis

3.1 DATA ANALYSIS

In order to study the changes occurring to the coastline, beaches in Christchurch Bay have been monitored on a regular basis (3 to 4 times per year) over 18 years. The monitoring has consisted of repeated measurements of the cross-section of the beach along a predefined beach profile. The monitoring, originally carried out by New Forest District Council, is currently carried out by the Channel Coastal Observatory (CCO) as part of the Regional Monitoring Programme for the South East of England. Beach profile data was obtained from the New Forest District Council database, which is regularly updated and maintained by the CCO. After reviewing all available data, the longest datasets were selected at various locations around Christchurch Bay. This would provide the highest amount of confidence regarding the identification of long term changes.

The beach provides a natural defence to wave erosion as beach material acts to dissipate wave energy. Although the existing coast protection measures around Christchurch Bay have successfully reduced the amount of erosion, the consequence to this is that as the amount of erosion has reduced the supply of material into the system has also declined. Defended sections, which contain cross-shore structures such as groynes, also act to trap material which is being transported under the process of long-shore drift. The effect that this can have is that undefended sections of coastline become progressively starved of sediment leading to an increase in the rate of erosion. Defended areas can also become affected by the reduction of sediment in the system. Reduced beach levels can lead to coastal defences becoming subject to an increased level of wave attack and increasingly more unstable due to the effect of unloading at the toe of the defence.

At each profile location all the survey data has been analysed to determine the position of the Mean Low Water (MLW) contour, the beach gradient and the cross-sectional area over time. This has enabled trends to be identified in order to qualify changes to the beaches around Christchurch Bay.

3.1.1 The position of the Mean Low Water contour

Each pre-defined beach profile is referenced to a zero point located landward of the coastline. The line extends positively seawards well beyond the toe of the beach. The level of the MLW contour has been defined as -0.78mOD. Where possible, the distance from the zero point to the MLW contour was measured for each survey and plotted against time at each location. A linear trend was added to highlight change over the time. An example of a MLW contour graph is given in Figure 3.1

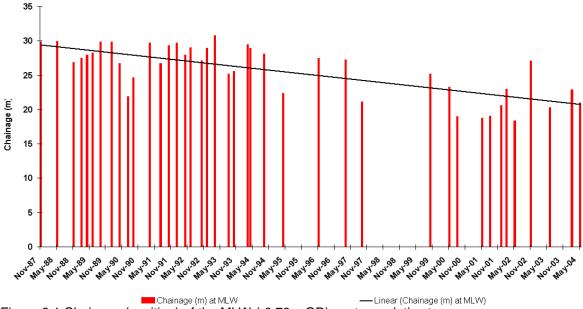

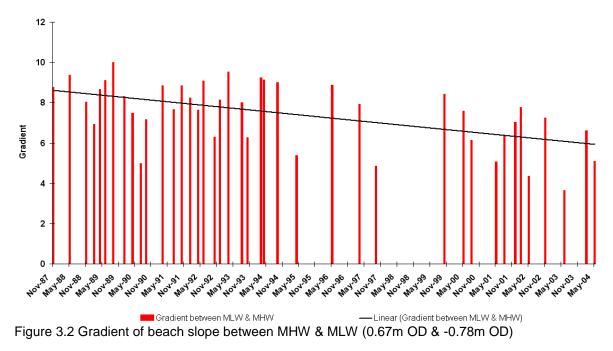

Figure 3.1 Chainage (position) of the MLW (-0.78m OD) contour relative to zero

3.1.2 Beach Gradient

The gradient within the inter-tidal zone is an indication of whether the beach is steepening or flattening. For each survey at each profile location the gradient of the beach was calculated between Mean High Water (MHW) (0.67mOD) and Mean Low Water (MLW) (-0.78mOD). The gradient value has been plotted against time and a trend line has been added. An example of a beach gradient graph is given in Figure 3.2.

3.1.3 Cross-sectional Area

The cross-section of the beach is an indication of the efficiency of the cross-shore structures and the amount of material available in the system. The cross-sectional area measured between MHW (0.67mOD) and MLW (-0.78mOD) has been calculated for each survey on each profile line. Linear trends have been determined. An example of a cross-sectional area graph is given in Figure 3.3.

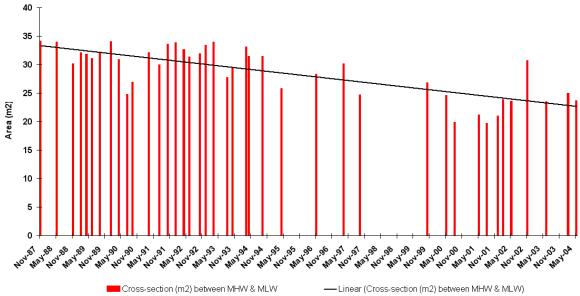

Figure 3.3 Cross-sectional area (m²) between MHW & MLW (0.67m OD & -0.78m OD)

Section D of the Appendix contains all graphs for the MLW position, gradient of the beach, and cross-sectional area at all profile locations around Christchurch Bay. Trends identified from the graphs in Section D of the appendix are summarised in Table 3.1 (below).

| | Profile Line | MLW position trend | Beach Gradient | Cross-sectional Area m2 |

Table 3.1 Trends identified from beach profile analysis

3.2 FORECASTING FUTURE DEFENCE FAILURE

Beach profile analysis has indicated that there are a number of locations around Christchurch Bay where the MLW contour (-0.78mOD) is regressing landwards. The trendline can be projected forward in order to predict where the future position of MLW is likely to be in order to assess the evolution of the Bay. This is illustrated in Figure 3.1.

In locations where along shore defences exist, the presence of a beach is important for the stability of the defence. Once the MLW contour reaches the toe of the defence (MLW expiry date), unless recharge material is added, the benefits offered by a beach are lost. This therefore results in an increased risk of structural failure occurring as the weight offered by the presence of a beach to the toe of the defence is reduced. In addition, wave energy will not be dissipated as effectively by the beach, the defence will be subject to an increased level of wave impact. Furthermore, without a beach in front of the defence, the potential for the along shore defence to reflect wave energy and induce scour in front of the defence is increased, thus intensifying the risk that structural failure will occur. Figure 3.4 (below) illustrates how the MLW expiry date is generated.

5f00091

Figure 3.4 MLW expiry date forecast (lower & average trend) for profile location 5f00091

Figure 3.4 indicates the trendline for the lower and average trend expiry date. The average trend expiry date is generated by extending the average (regression) trendline (coloured light blue in figure 3.4) into the future until it meets the defence toe chainage position (i.e. the point in the future when MLW coincides with the toe of the defence). The lower trend expiry date has been generated to take into account the contribution of beach draw down caused by seasonal variation or following storm events. Over the period the profile has been surveyed, there has been a significant deviation between the recorded chainage position and the average trendline position. The lower deviation is important as it represents a scenario when the MLW is significantly closer to the toe of the defence (in comparison with the average trend rate). Although the MLW position is not maintained, during these periods the risk of structural failure is considerably increased. Therefore in order to take the lower deviation into account the lowest recorded deviation is selected and the trendline applied to this lower level (coloured dark blue in figure 3.4). The lower trend line is again projected into the future until it meets the defence toe chainage position. Lower and average trend expiry dates have been calculated at all profile locations where regression has been identified and the complete results are presented in Appendix E (Table E.1). A summary of the results is presented in Table 3.2 (below).

| | Profile Line | MLW position forecast |
|------|--------------|--|
| CBY6 | 5f00070 | Stable / no change |
| | 5f00076 | MLW to reach toe of defences between 2024 & 2053 |

Table 3.2 MLW position trend forecast

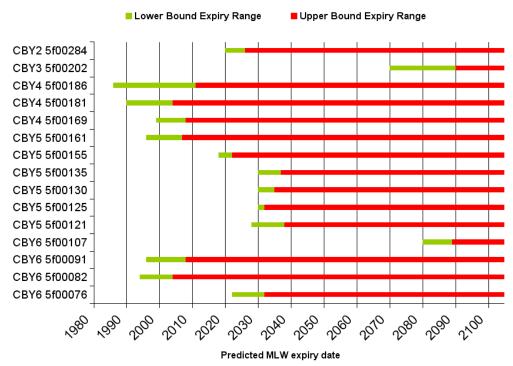

Figure 3.5 Lower and upper bound expiry dates

Figure 3.5 is a timeline which highlights when the lower and average trendlines are predicted to coincide with the toe of the defence. The start of the green bar in Figure 3.5 represents the earliest predicted date that MLW will reach the toe of the structure (taken from the lower trendline projection). The start of the red line is the predicted date when MLW will reach the toe of the structure (taken from the average trendline projection).

Table 3.3 MLW expiry date comparison

Table 3.3 is a comparison between the predicted date of failure following the condition assessment undertaken in the field and the predicted expiry date derived from beach profile analysis trendline interpretation.

3.3 BEACH PROFILE ANALYSIS SUMMARY

Two methods have been used to estimate the residual life of along-shore defences. Although the MLW expiry date is not the actual date of failure, for the purpose of assessing the residual life of the defences within the 'Do Nothing' scenario, the MLW expiry date will be used in the same terms the residual life, as the risk of structural failure is significantly higher. Table 3.3 can therefore be used to compare results from the two methods in order to justify the residual life estimates generated by the condition assessment.

Beach profile analysis indicates that the MLW contour is regressing in all three sections of defended coastline. Although there is variability, in Unit CBY4 and Unit CBY6 there appears to be good correlation between the MLW expiry date and the residual life expiry date identified from the condition assessment. There is a long comprehensive dataset of beach profile data for the profiles in Unit CBY4 and Unit CBY6, thus providing considerable confidence in the analysis. Within Unit CBY4, a number of profiles have indicated that the lower expiry date has been passed and that the average expiry date has been reached. These profiles are located in a section of coastline where the wall has failed and that rock revetment has had to be placed in front of the wall in order to extend the life of the wall. The residual life of the defence has therefore been based on the residual life of the revetment structure.

The correlation between the two methods in Unit CBY2 is less positive than Unit CBY4 and Unit CBY6, however correlation does exist between the methods at profile 5f00284. The defence needs to remain intact in order for integrity of the unit to be preserved. If a section were to fail this would weaken the defence and increase the risk of further failures occurring. In addition, the beach profile dataset for this section is less comprehensive therefore reducing the confidence in the results.

Annex C: Asset Condition Summary per Management Unit

C1 Strategic Management Unit CBY1 A&B

| CT Strategic Management Unit CBTT A&D | |
|---------------------------------------|---|
| | Plate C1.1 Looking south, view of concrete revetment on west side of beach frontage |
| | Plate C1.2 Looking south, view of wooden revetment on eastern side of dunes |
| | Plate C1.3 Looking south, view of rock groynes at the southern end of Mudeford Spit |
| | Plate C1.4 Looking south, view of rock groyne, Mudeford Spit |

| Boundaries of Management Unit | Hengistbury Long Groyne to tip of Mudeford Sandbank |
|-------------------------------|--|
| Total frontage length (m) | 1860 |
| Defended frontage length (m) | 1860 |
| Current SMP policy | Hold the Existing Defence Line |
| Current beach condition | Beach recycling programme in operation |
| | Stable sand spit, profile maintained through maintenance |
| | No change or slight erosion in cross-sectional area |
| | No change in MHW contour position |
| | Seaward face dynamic and mobile |
| | Hengistbury Head shelters Spit from prevailing south westerly waves |
| Existing Management Schemes | Mudeford Sandbank Management Plan details the maintenance of the |
| | entire spit for a 50-year period |
| Along Shore Defences | There are 6 sections of along-shore defence: |
| | 5 sections are comprised of Portland limestone revetment, comprising |
| | 1-3 ton rock units, with a residual life ranging from 10 to 30 years |
| | There is 1 wooden revetment section, with a residual life of |
| | approximately 10 years |
| Cross Shore Structures | There are 19 cross-shore structures: |
| | All cross-shore structures are rock groynes constructed of 1-3 ton |
| | Portland limestone armour units with residual life values ranging from |
| | 10 to 20 years |

| Accet owned by | Obviotely web Developed Occurreit |
|-------------------------------|---|
| Asset owned by | Christchurch Borough Council |
| Asset maintained by | Christchurch Borough Council |
| Hinterland | Mudeford Spit is a natural geomorphological feature that extends north/northeast from the eastern end of Hengistbury Head promontory The combination of the headland and spit provides protection to the towns of Christchurch and Mudeford, and the low-lying land bordering the shallow harbour and the banks of the Rivers Stour and Avon. To the east of the Spit is Christchurch Bay, with a dynamic shallow sandbank at its northern end; this is often exposed, and restricts navigation to a single channel (the 'Run') which experiences significant tidal current velocities. There are approximately 350 beach huts located on the spit |
| Health and Safety Issues | None identified |
| Current Maintenance Programme | As detailed in the Mudeford Sandbank Management Plan |

C3 Strategic Management Unit CBY3

Plate C3.1 Looking southwest, view of undefended frontage at Naish Farm

| Boundaries of Management Unit | Chewton Bunny to western end of Barton-on-Sea defences |
|-------------------------------|---|
| Total frontage length (m) | 1270 |
| Defended frontage length (m) | 0 |
| Current SMP policy | Managed Retreat |
| Current beach condition | Dynamic and mobile mixed shingle and sand beach |
| Existing Management Schemes | |
| Along Shore Defences | None |
| Cross Shore Structures | None |
| Asset owned by | Beach and cliffs - New Forest District Council |
| Asset maintained by | Beach and cliffs - New Forest District Council |
| Hinterland | The undefended, geologically important soft mud cliffs are approximately 30m in height. There is a Holiday Village (caravan and chalets) on the cliff top The cliffs respond rapidly to the groundwater levels following rainfall and storm wave events, exhibiting mass movement, seepage erosion, and rotational slumping |
| Health and Safety Issues | Potential hazard involving public accessing exposed soft cliff surface |
| Current Maintenance Programme | |

C4 Strategic Management Unit CBY4

| Plate C4.1 Looking northeast, view of rock revetment and cliff stabilisation structures at Barton-on-Sea |
|--|
| Plate C4.2 Looking east, view of rock revetment and groynes at Barton-on-Sea |

| Boundaries of Management Unit | Western end of Barton-on-Sea defences to Barton-on-Sea Golf |
|-------------------------------|--|
| | Course |
| Total frontage length (m) | 1887 |
| Defended frontage length (m) | 1887 |
| Current SMP policy | Hold the Existing Defence Line |
| Current beach condition | Shingle and sand beaches of limited extent have formed within some groyne cells |
| | Results from analysis of beach profiles measured over the period 1989 to 2004 indicate that the beach width (from MLW contour position) has varied by 3 to 4m, and the beach slope trend over this period indicates slight steepening |
| Existing Management Schemes | |
| Along Shore Defences | There are 2 sections of along-shore defence: Both sections consist of Mendip limestone armour rock revetment comprised of 3-6 ton rock units which protect the toe of the cliff with a residual life ranging from 5 to 30 years |
| Cross Shore Structures | There are 6 cross-shore structures: All 6 structures are rock strongpoints comprised of 2-4 ton Mendip limestone rock units with residual life ranging from 10 to 15 years |
| Asset owned by | New Forest District Council |
| Asset maintained by | New Forest District Council |
| Hinterland | The majority of the residential and commercial properties are set back from the cliff edge behind a recreational area of grass and the cliff top highway. Due to continuing cliff erosion a number of properties are now located nearer to the cliff edge Extensive cliff stabilisation measures have been installed within this unit including re-profiling of the cliff slope and the installation of sheet pile cut-off walls and drainage. Much of these works have been |
| | affected by cliff movement and the process of erosion, as a result their functionality and performance is likely to have reduced in effectiveness |
| Health and Safety Issues | Access tracks have been closed between Sea Road and Hoskins Gap due to ground movement and there is the potential hazard associated with public accessing exposed soft cliff surface |
| Current Maintenance Programme | |
| | |

C5 Strategic Management Unit CBY5

| Plate C5.1 Looking east, view of undefended frontage at Becton, east of Strong Point 25 at Barton-on-Sea |
|--|
| Plate C5.2 Looking east, coastline to the east of Strong Point 25 at Barton-on-Sea |

| Boundaries of Management Unit | Barton Golf Course to Hordle Cliff |
|-------------------------------|--|
| Total frontage length (m) | 2461 |
| Defended frontage length (m) | 0 |
| Current SMP policy | Do Nothing (observe and monitor) |
| Current beach condition | Generally stable wide, gently sloping shingle and sand beach, gently sloping to cliff toe Results from analysis of beach profiles measured over the period 1989 to 2004 indicate that the beach width (from MLW contour position) has varied by 6m, with an annual trend of beach cross-section area reduction. The beach slope trend over this period indicates no change |
| Existing Management Schemes | |
| Along Shore Defences | None |
| Cross Shore Structures | None |
| Asset owned by | Private Land Owners |
| Asset maintained by | Private Land Owners |
| Hinterland | The cliff top land is primary used for agriculture and golf course. The only development, located at the eastern end of the frontage, is set back from the cliffs near Milford The Becton Bunny outfall which is located to the west of the section has been protected with armourstone for the past 20years. The defence has acted in a similar manner to a groyne and has led to an increased amount of erosion to the east of the outfall, however the outfall was becoming outflanked due to cliff erosion. The bulk of the concrete cofferdam structure was removed in Autumn 2004 to be replaced by a submerged pipe to the west. Rock units still remains at the site of the original outfall |
| Health and Safety Issues | Access across/around Becton Bunny over existing rock Footpath repositioning following erosion of cliff |
| Current Maintenance Programme | |

C6 Strategic Management Unit CBY6

| Plate C6.1 Looking west, view of wooden groynes and concrete seawall at Milford-on-Sea, together with concrete beach huts |
|--|
| Plate C6.2 Looking west, view of concrete seawall and wooden groynes at Milford-on-Sea, together with timber beach huts |

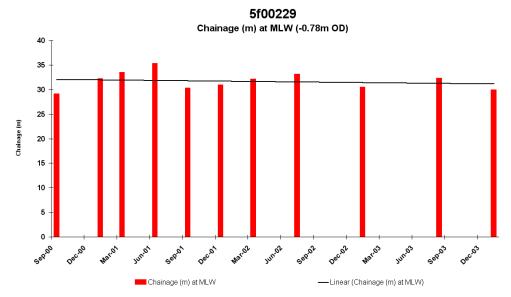

| Boundaries of Management Unit | Hordle Cliff to Hurst Beach |
|-------------------------------|--|
| Total frontage length (m) | 2347 |
| Defended frontage length (m) | 2347 |
| Current SMP policy | Hold the Existing Defence Line |
| Current beach condition | Dynamic shingle and sand beach |
| | Results from analysis of beach profiles measured between 1987 & 2004 indicate that the beach width (from MLW contour position) has varied by 13m, with an annual trend of beach cross-section area reduction. The beach slope trend over this period indicates no change |
| Existing Management Schemes | |
| Along Shore Defences | There are 11 sections of along-shore defence: 9 sections consist of sloping / vertical concrete seawalls with a residual life of between 5 to 20 years which offer protection to low cliffs. In addition there are 2 sections of rock revetment composed of a mixture of Mendip & Portland limestone rock unit which offer protection to the toe of the seawalls. The sections of revetment have a residual life ranging between 10 & 20 years |
| Cross Shore Structures | There are 27 cross-shore defences: 3 structures are constructed of Mendip and Portland limestone rock strongpoints with a residual life ranging between 5 & 30 years |
| | There are 24 hardwood pile and board groynes with a residual life ranging between 2 & 10 years |
| Asset owned by | New Forest District Council |
| Asset maintained by | New Forest District Council |
| Hinterland | The predominantly residential village of Milford-on-Sea is fronted by a strip of undeveloped open space and recreational land. There are soft cliffs to the west of the unit gradually reducing in elevation to the east The low-lying land to the west side of Sturt Pond is a flood risk area There are approximately 140 beach huts (concrete and timber) along this frontage |
| Health and Safety Issues | None identified |
| Current Maintenance Programme | Milford Promenade Improvements Works Groyne maintenance programme |

C7 Strategic Management Unit CBY7

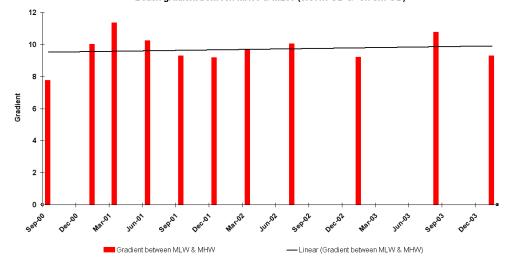

| Plate C7.1 Looking west, view of offshore rock breakwater, Hurst Spit |
|--|
| Plate C7.2 Looking northeast, view of wooden revetment and groynes west of Hurst Castle, Hurst Spit |
| Plate C7.3 Looking northwest, view of wooden groynes and rock revetment on south side of Hurst Castle, Hurst Spit |

| Strategic Management Unit | CBY7 |
|-------------------------------|---|
| Boundaries of Management Unit | Hurst Spit |
| Total frontage length (m) | 2893 |
| Defended frontage length (m) | 2893 |
| Current SMP policy | Hold the Existing Defence Line |
| Current beach condition | Shingle spit, profile managed through maintenance, and periodic recycling of shingle from tip of recurve (North Point) No change in cross-sectional area as the Spit is maintained No change in MHW contour position Seaward face experiences dynamic volumetric changes due to storm wave events and is therefore beach sediment is highly mobile Leeward face of the spit is stable |
| Existing Management Schemes | Hurst Spit Beach Management Plan details the maintenance of the entire spit for a 50-year period |
| Along Shore Defences | Hurst Castle receives protection from a mixture of defences including hardwood pile and board revetments with residual life ranging from 5 to 20 years, and Mendip armour and Portland limestone rock revetments with residual life ranging from 10 to 50 years At the foot of the Spit an offshore breakwater and 400m section of revetment, each with a residual life of 50 years, were constructed in 1996 comprising Norwegian Larvic 6-10 ton and 3-6 ton rock units, respectively |
| Cross Shore Structures | In addition to the defences described above the castle also receives protection from hardwood pile and board groynes with residual life of 1 to 25 years |
| Hinterland | Christchurch Bay is to the south and west of Hurst Spit, with Hurst Narrows immediately offshore of Hurst Castle. The Spit protects the entire West Solent In the lee of the Spit (the eastern side) is the Keyhaven estuary, containing saltmarshes, inter-tidal mudflats and creek/channel networks |
| Health and Safety Issues | None identified |
| Current Maintenance Programme | As detailed in the Hurst Spit Beach Management Plan |
